¹¹ Summary

¹² We present sensipy, an open-source Python toolkit for simulating observations of transient
¹³ astrophysical sources, particularly in the high-energy (HE, keV-GeV) and very-high-energy
¹⁴ (VHE, GeV-TeV) gamma-ray ranges. The most explosive events in our universe are often
¹⁵ short-lived, emitting the bulk of their energy in a relatively narrow time window. Due to often
¹⁶ rapidly fading emission profiles, understanding how and when to observe these sources is crucial
¹⁷ both to test theoretical predictions and efficiently optimize available telescope time.

¹⁸ The information extracted from the tools included in sensipy can be used to help astronomers
¹⁹ investigate the detectability of sources considering various theoretical assumptions about their
²⁰ emission processes and mechanisms. This information can further help to justify the feasibility
²¹ of proposed observations, estimate detection rates (events/year) for various classes of sources,
²² and provide scheduling insight in realtime during gamma-ray and multi-messenger observational
²³ campaigns.

²⁴ Statement of need

²⁵ The need for a toolkit like sensipy became clear while attempting to estimate the detectability
²⁶ of VHE counterparts to gravitational wave (GW) signals from binary neutron star mergers
²⁷ (BNS) with the upcoming Cherenkov Telescope Array Observatory (CTAO) ([Green et al., 2024](#);
²⁸ [Patricelli et al., 2022](#)). During development, it became apparent that the included tools could
²⁹ be applied not only to VHE counterparts of BNS mergers, but also to other transient sources
³⁰ like gamma-ray bursts (GRBs), active galactic nuclei flares, novae, supernovae, and more.

³¹ Between GW, neutrino, optical, and space-based gamma-ray experiments, thousands of low-
³² latency alerts are sent out to the greater community each year ([Abac et al., 2025](#); [Abbasi et al.,](#)
³³ [2023](#); [Kienlin et al., 2020](#)). However, very few of these events actually result in detections in the
³⁴ VHE gamma-ray regime. This is due to many factors, including the rapid decay of fluxes, delay
³⁵ in telescope repointing, uncertainty on the sky localization of the source, and observatory duty
³⁶ cycles. In the face of these challenges, sensipy aims to help answer the following questions
³⁷ for gamma-ray astronomers interested in optimizing their follow-up campaigns:

- ³⁸ ▪ Given a theoretical emission model, what are the detection possibilities with a given
³⁹ instrument?
- ⁴⁰ ▪ How much observing time is needed to detect a source given a delay in starting
⁴¹ observations?

- 42 ▪ At what significance level is a source detectable given a certain observation time?
- 43 ▪ How long does a source remain detectable after the onset of emission?
- 44 ▪ How can intrinsic source properties (e.g. distance, flux) and observing conditions
- 45 (e.g. latency, telescope pointing) affect detectability?
- 46 ▪ How can these results for catalogs of simulated events inform follow-up strategies in
- 47 realtime?

48 **Functionality**

49 The two main inputs to any sensipy pipeline are:

- 50 ▪ an instrument response function (IRF), which describes how a telescope performs under
- 51 specific observing conditions.
- 52 ▪ intrinsic time-dependent emission spectra for a source, which can be provided in either a
- 53 FITS or CSV format.

54 Given these inputs, sensipy builds upon primitives provided by astropy and gammapy to

55 provide the following main functionalities ([Donath et al., 2023](#); [The Astropy and Price-Whelan](#)

56 [Collaboration et al., 2022](#)). In addition, mock datasets are provided with working code examples,

57 and batteries are included for easy access to publicly-available IRFs, e.g. ([Cherenkov Telescope](#)

58 [Array Observatory and Consortium, 2021](#)).

59 **Sensitivity Curve Calculation with `sensipy.sensitivity`**

60 Sensitivity curves represent the minimum flux needed to detect a source at a given significance

61 (usually 5σ) given an exposure time t_{exp} . Such curves are often used to compare the

62 performances of different instruments, and sensipy can produce them in two flavors: integral

63 and differential sensitivity curves. The sensitivity itself depends heavily on the rapidly-changing

64 spectral shape of an event, which itself may be highly affected by distance due to the

65 extragalactic background light (EBL). All of these factors are automatically taken into account.

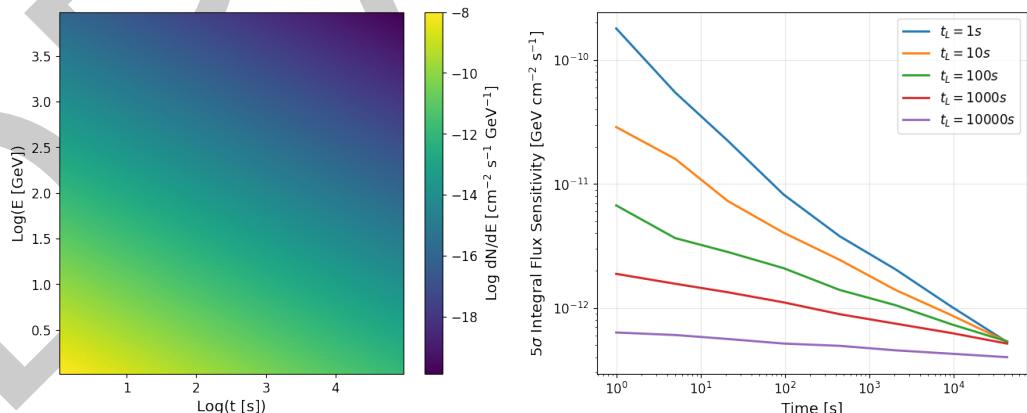

Figure 1: A 2-D representation of the intrinsic time-dependent VHE gamma-ray flux for an example transient event (left) and the corresponding integral flux sensitivity of CTAO for a source with this spectrum (right). The sensitivity curves are calculated for different latencies (t_L) after the event onset.

66 **Simulating Observations with `sensipy.source`**

67 This class addresses the fundamental question: if we begin observations with a latency of

68 $t_L = X$ min after an alert, what observation time is required in order to achieve a detection?

69 In addition, the class can also determine the inverse: given an observation time, at what

70 significance can a source be detected? Given that the user has already calculated the sensitivity

⁷¹ curve for an event, sensipy can determine if the source is actually detectable, given t_L . When
⁷² detectable, the exposure time necessary for detection is also calculated.

⁷³ Working with large catalogs with `sensipy.detectability`

⁷⁴ sensipy can further estimate the overall detectability of entire classes of objects, given a
⁷⁵ catalog or survey of simulated events under various conditions. By performing and collating a
⁷⁶ large number of observation simulations for various events and latencies t_L , the toolkit can
⁷⁷ help produce visualizations which describe the optimal observing conditions for such events.

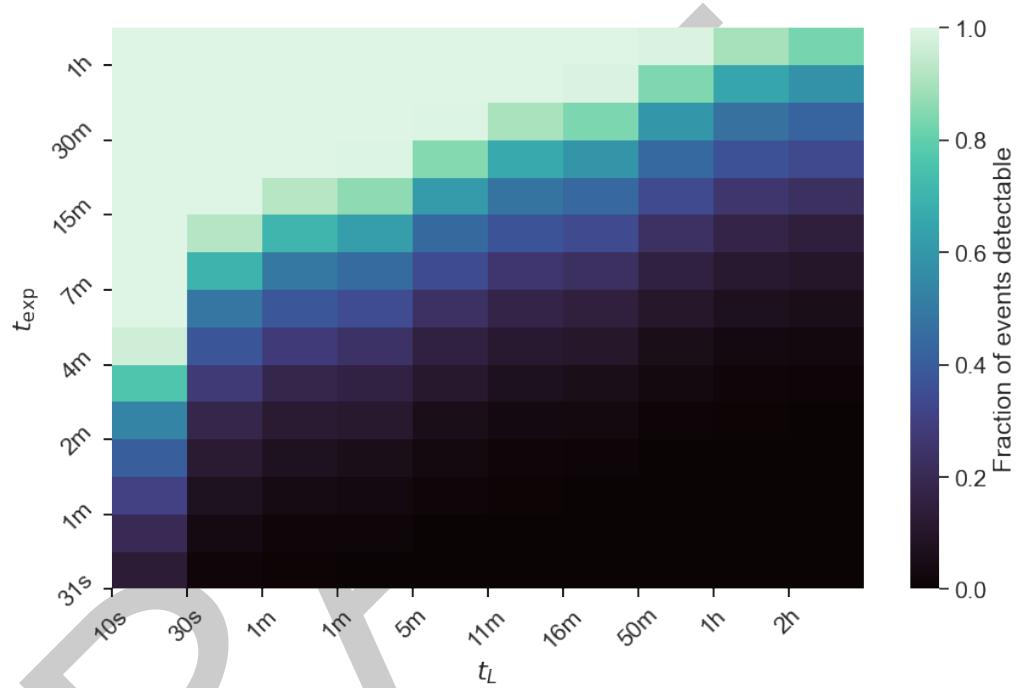

Figure 2: Detectability heatmap produced with sensipy. Given a large catalog of transient events, this sensipy heatmap shows what fraction are potentially detectable given a specific observation time t_{exp} and latency t_L since the event onset.

⁷⁸ Realtime applications with `sensipy.followup`

⁷⁹ Tables of observation times can also be used as lookup tables (LUTs) during telescope
⁸⁰ observations in order to plan observation campaigns. For example, the following workflow can
⁸¹ be implemented within sensipy:

- ⁸² 1. a catalog of simulated spectra is processed with the above pipeline considering various
⁸³ observation conditions, and a LUT is created
- ⁸⁴ 2. a transient alert arrives during normal telescope operation and telescopes begin observing
⁸⁵ the event position with a latency of t_L
- ⁸⁶ 3. the LUT is filtered and interpolated in realtime in order to quickly calculate an informed
⁸⁷ estimate on the exposure time needed for a detection

⁸⁸ Such workflows based on sensipy modules are already being internally evaluated within the
⁸⁹ MAGIC, Large-Size Telescope (LST), and CTAO collaborations for follow-up of both GW and
⁹⁰ GRB alerts (e.g., [Green et al., 2024](#); [Patricelli et al., 2022](#)).

91 Follow-ups of poorly localized events

92 In addition, the functions included in `sensipy.followup` may be used in tandem with scheduling
 93 software like `tilepy` for the realtime follow-up of poorly-localized events, including GRB, GW,
 94 and neutrino alerts (Seglar-Arroyo et al., 2024). These scheduling tools create an optimized
 95 list of telescope pointings on the sky, while `sensipy` is used simultaneously to optimize the
 96 exposure time needed at each new pointing.

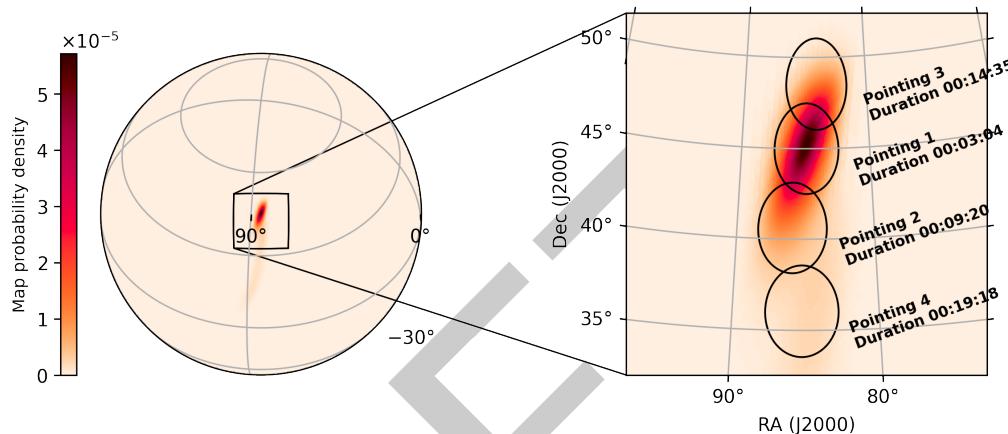

Figure 3: A follow-up coverage map for an example GW event (S250704ab). The ordering of pointings is calculated by `tilepy` and the optimal observing time at each pointing by `sensipy`.

97 AI usage disclosure

98 AI tools (GitHub Copilot, Grammarly) were used to proofread documentation and pull requests
 99 as well as scaffold tests. Instances where functions or classes were primarily generated with
 100 assistance from GitHub Copilot (auto model) are explicitly marked in the Python docstrings. All
 101 AI-assisted suggestions were carefully reviewed and approved by the authors of this manuscript.
 102 AI tools were not used in the writing of this manuscript in any capacity.
